Spotify Dataset Cleaning Report

Predictive Analytics Project • Prepared 26 October 2026

1. Dataset overview

The dataset was reported to contain 8,582 records and 15 columns. The cleaning described here focuses on missing-value handling and duplicate checks; it is not a guarantee that every value is valid or suitable for modeling.

Check	Before	After	Notes
Records	8,582	8,582	Rows preserved
Columns	15	15	Columns preserved
Missing artist_genres	3,361	0	Replaced with “Unknown”
Missing artist_name	3	0	Replaced with “Unknown Artist”
Duplicate rows	0	0	No rows removed for duplicates
Missing cells (reported)	3,364	0	Based on the earlier inspection

2. Cleaning actions

Missing genres: Missing `artist_genres` entries were filled with “Unknown” rather than inventing genre labels.

Missing artist names: Missing `artist_name` entries were filled with “Unknown Artist”.

Duplicates: The initial inspection found no duplicate rows or duplicate track IDs, so no rows were removed for duplication.

Preservation: The reported cleaning kept all 8,582 rows and all 15 columns.

3. Checks still recommended before modeling

• Validate ranges and types for every column, not just selected columns.
• Investigate unusually short/long track durations and unusual dates.
• Check whether popularity columns are appropriate predictors for the target to avoid leakage.
• Split data into training/test sets before fitting scalers or other preprocessing steps.
• Keep the original file unchanged and document all cleaning decisions.

4. Important limitation

This report summarizes the cleaning figures previously reported in the conversation. The file itself has not been independently re-audited while generating this PDF. Treat the counts as provisional until they are rechecked against the saved cleaned CSV.

Recommended next step: verify the cleaned CSV's row count, column names, missing values, and value ranges, then upload it to GitHub with a clear commit message.
